INTRODUCTION

Scabies is a contagious skin disease caused by infestation with the ectoparasite Sarcoptes scabiei var. hominis. The mite burrows and lays eggs under the skin, thus causing severe itch. The condition adversely affects the daily lives of patients and their cohabitants. Approximately 200 million people suffer from scabies worldwide. In Korea, scabies accounted for 3.2~9.1% of the outpatient visits at dermatology departments in the 1970s~1980s. In the 1970s, the spread of
scabies most commonly occurred in homes, lodgings, and dormitories. However, since the 1980s, there has been an increased incidence of its spread within long-term care hospitals (LTCHs)\(^4,5\). In a multicenter study of Korean patients with scabies (n = 914) conducted in the early 2010s, transmission from family members was found to account for 64% of cases, followed by LTCHs (25.7%)\(^6\). The most recent epidemiologic study on scabies in Korea was based on the National Health Insurance (NHI) claims database from 2010 to 2017\(^7\). The study reported the highest annual incidence of 2.9–3.86 per 1,000 people among individuals aged ≥80 years. However, the study did not report age-standardized incidence rates. Moreover, the social distancing measures implemented during the COVID-19 pandemic may have influenced the spread of scabies, since social contact is highly associated with the spread of the disease.

Therefore, the aim of this study was to update the epidemiologic profile of scabies in Korea by analyzing the NHI claims database for the period 2010–2021. Moreover, age-standardized incidence rates (ASRs), to adjust for the effect of an aging population, and regional incidence rates are reported.

**MATERIALS AND METHODS**

This was a nationwide population-based observational study using the NHI claims database which covers up to 98% of the Korean population. Patients with at least one claim record with a diagnostic code (International Classification of Diseases 10th revision) of B86 from 2010 to 2021 were defined as incident cases in the corresponding years. The study population was collected from the resident registration population data released annually by Statistics Korea (http://kosis.kr).

The primary outcome measure was the annual incidence of scabies between 2010 and 2021. The crude incidence rates (CRs) were calculated as the total number of incident cases divided by the study population in the corresponding years. The study population was divided into 10-year age groups and age-specific incidence rates were calculated by dividing the number of incident cases in the age group by the number of corresponding person-years (PYs). The ASRs were calculated as the sum of the weighted incidence rates for each age group by using Segi’s world standard population. The average annual percent change (AAPC) is the weighted average of the annual percent change in the ASRs over a period and was calculated using the formula \((\exp(b) - 1) \times 100\), where \(b\) is the slope of the regression of the natural log-transformed ASR from the linear regression equation \(E(\log(\text{ASR}) | \text{year}) = a + b \times \text{year}\). Subgroup analysis was performed by sex, 10-year age groups (0–9, 10–19, 20–29, 30–39, 40–49, 50–59, 60–69, 70–79, and ≥80 years), and region of residence.

This study was exempted from review by the Institutional Review Board (IRB) of Kyung Hee University Hospital at Gangdong in accordance with the exemption criteria (IRB No. 2023-10-034).

**RESULTS**

1. Incident cases

Between 2010 and 2021, a total of 517,296 incident cases of scabies were identified. There were 234,255 males and 283,041 females, with a male-to-female ratio of 0.83. The annual number of scabies cases showed a progressive de-

---

www.e-jmi.org
increase during the study reference period. The number of scabies cases in 2010 and 2021 were 51,331 and 29,693, respectively, which corresponded to a 42.2% decrease (Fig. 1). A steep reduction (>10%) in the incident cases compared with the preceding year was observed in 2015 (-10.3%), 2020 (-11.2%), and 2021 (-18.8%). The male-to-female ratio steadily decreased from 2010 (0.99) to 2021 (0.64).

Fig. 2 shows the age distribution of patients with scabies. An aging trend was observed in patients with scabies from 2010 to 2021. In 2010, the 40~49 years age group accounted for the largest proportion of patients (16.4%), followed by the 50~59 years age group (15.3%), 20~29 years age group (14.2%), and 30~39 years age group (14.0%). In 2021, the largest proportion of patients was in the 60~69 years age group (21.0%), followed by the 50~59 years age group (20.3%), ≥80 years age group (12.4%), and 40~49 years age group (11.5%). Patients aged ≥50 years accounted for 36.5% of the incident cases of scabies in 2010, and this figure increased to 63.8% in 2021.

2. Crude incidence rate

The annual CR of scabies steadily decreased by 43.8% from 2010 (102.9 per 100,000 PY) to 2021 (57.8 per 100,000 PY) (Fig. 3). A steep decrease in the annual CR (>10%) compared with the preceding year occurred in 2015 (-10.6%), 2020 (-11.2%), and 2021 (-18.8%).

3. Age-standardized incidence rate

The annual ASR of scabies steadily decreased from 2010 (97.6 per 100,000 PY) to 2021 (43.4 per 100,000 PY), with
Fig. 5. Age-specific incidence rates and average annual percentage change in incidence of scabies in Korea, 2010–2021

Fig. 6. Regional distribution of scabies in Korea, 2010–2021

an AAPC of -5.0% (Fig. 4). When the period corresponding to the peak of COVID-19 pandemic (2020–2021) was excluded, the annual ASR showed a decreasing trend from 2010 to 2019 (64.4 per 100,000 PY), with an AAPC of -3.8%.
A steep decrease in the annual ASR was observed in 2015 (-12.9%), 2020 (-12.7%), and 2021 (-22.8%).

4. Age-specific incidence rate

The ≥80 years age group showed the highest age-specific incidence rate during the study period, which decreased from 386.1 per 100,000 PY in 2010 to 181.5 per 100,000 PY in 2021 (AAPC, -4.8%) (Fig. 5). In 2010, high incidence rates of scabies were observed in the younger age groups, including the 20–29 years age group (105.2 per 100,000 PY), 40–49 years age group (96.9 per 100,000 PY), and 10–19 years age group (87.6 per 100,000 PY). By contrast, in 2021, the age groups beyond the threshold of 50 years showed high incidence rates: 60–69 years age group (90.5 per 100,000 PY), 70–79 years age group (87.6 per 100,000 PY), and 50–59 years age group (79.6 per 100,000 PY) had the highest incidence rates following the ≥80 years age group.

All age groups showed a reduction in incidence rates from 2010 to 2021. However, the extent of reduction was relatively greater in young patients (≤50 years) than in old patients (≥50 years): 10–19 years (AAPC, -6.6%), 0–9 years (AAPC, -6.0%), and 20–29 years (AAPC, -5.4%) compared with 60–69 years (AAPC, -0.6%), 50–59 years (AAPC, -3.6%), and 70–79 years (AAPC, -3.6%). Among the age groups beyond 50 years, the incidence in the 60–69 years age group in 2021 was comparable to that in 2010 (AAPC, -0.6%). After excluding the period corresponding to the COVID-19 pandemic peak, the 60–69 years age group showed an increase in incidence from 96.4 per 100,000 PY in 2010 to 121.3 per PY in 2019, with an AAPC of 2.9%.

5. Regional incidence rate

Fig. 6 shows the regional distribution of patients with scabies. Gyeonggi accounted for the highest proportion of patients during the study period (24.1% in 2010 and 21.3% in 2021), followed by Seoul (17.6% in 2010 and 12.9% in

*Top 5 regions where incidence of scabies was the highest in the corresponding year
Epidemiology of Scabies in Korea (2010–2021): An Updated Report
Y-j Lee, et al.

2021) and Busan (7.3% in 2010 and 8.6% in 2021).

Table 1 shows the regional incidence rates of scabies. In 2010, Gwangju showed the highest incidence (185.2 per 100,000 PY), followed by Jeju (157.6 per 100,000 PY), Jeonnam (139.5 per 100,000 PY), Daejeon (125.7 per 100,000 PY), and Jeonbuk (116.2 per PY). In 2021, these five provinces still had the highest incidence rates: Gwangju (97.0 per 100,000 PY), Jeonbuk (89.0 per 100,000 PY), Jeju (80.9 per 100,000 PY), Jeonnam (80.4 per 100,000 PY), and Daejeon (78.6 per 100,000 PY).

DISCUSSION

This nationwide population-based observational study revealed a steady decrease in the incidence of scabies in Korea in all age groups over the last 12 years. Prominent reductions in the incidence of scabies were observed in 2015 and 2020–2021, which corresponded to the outbreaks of the Middle East Respiratory Syndrome (MERS) and COVID-19, respectively. A trend of progressive aging of patients was noted during the study period, with patients aged ≥50 years accounting for 36.5% and 63.8% of cases in 2010 and 2021, respectively. Seoul and Gyeonggi had the highest number of patients with scabies, although the incidence was high in other regions.

The increasing trend of nuclear and single-member families, improved general hygiene, and growing recognition of scabies in LTCs may have led to a decrease in the incidence of scabies. Given that scabies spreads via close contact, family members and cohabitants of patients are at a high risk of developing scabies. In an analysis of 914 patients with scabies, transmission from a family member was reported in 68% of cases in 2010 and 2021, respectively. Seoul and Gyeonggi had the highest number of patients with scabies, although the incidence was high in other regions.

The increasing trend of nuclear and single-member families, improved general hygiene, and growing recognition of scabies in LTCs may have led to a decrease in the incidence of scabies. Given that scabies spreads via close contact, family members and cohabitants of patients are at a high risk of developing scabies. In an analysis of 914 patients with scabies, transmission from a family member was reported in 68% of cases in 2010 and 2021, respectively. Seoul and Gyeonggi had the highest number of patients with scabies, although the incidence was high in other regions.

The two outbreaks of respiratory infectious diseases, namely, MERS in 2015 and COVID-19 in 2020–2021, helped improve the general hygiene practices among the population. During the MERS outbreak, handwashing was emphasized, and social contact was discouraged, thus causing a steep decrease in scabies cases in 2015. However, these results were not sustained after the outbreak, as shown by the comparable incidence of scabies from 2016–2019 to 2015. Owing to the more profound impact of COVID-19 than MERS in terms of its duration and the implementation of social distancing measures, the incidence of scabies was the lowest during the COVID-19 pandemic. Further epidemiological studies on scabies after the COVID-19 pandemic are required to determine whether the dramatic decrease in incidence has been sustained.

The epidemiology of scabies is associated with the socioeconomic status of a country. Considering that poor hygiene, overcrowding, and malnutrition are risk factors for scabies, developing countries have a high incidence of scabies in early childhood, and the incidence decreases in adulthood. By contrast, developed countries have a low incidence of scabies in all age groups. However, localized outbreaks of scabies in LTCs occur in developed countries with well-established facilities for the elderly. According to a retrospective analysis, LTCs accounted for 48% of institutional scabies outbreaks. The current study revealed a unique epidemiological characteristic of scabies in Korea in that the highest incidence was observed in elderly individuals. The phenomenon of progressive aging of these patients was observed over the last 12 years. In contrast to the even distribution of scabies among individuals aged 20–50 years in the early 2010s, the proportion of elderly patients rapidly increased until 2021. A prominent increase in the proportion of patients was noted in the 60–60 years age group and ≥80 years age group.

The number of LTCs in Korea has rapidly increased after the initiation of long-term care insurance by the Korean government in 2008. In 2018, the number of registered LTCs in Korea was 1,450, an increase of 8% each year. According to a survey, 71.8% of LTCs in Korea have reported scabies cases in the last five years. These outbreaks were attributed to several factors such as delayed diagnosis, lack of separation, shortage of personal protective equipment for personnel, inadequate recognition and health education regarding scabies, and frequent transfer of patients to other facilities or LTCs. The average duration from the initial presentation of symptoms to the diagnosis of scabies was one week. Delayed diagnosis might result from nonspecific manifestations or complications, such as secondary bacterial infection in elderly patients, high prevalence of comorbid diseases that impair cognition, and limited diagnostic tools for scabies. Only 50% of patients with scabies were treated in scabies-restricted rooms, and 32.2% of medical staff who had contact with patients developed scabies because of the insufficient supply of personal protective equipment.

Although concerns regarding infection control were raised in the early stages, an evaluation conducted in 2011 showed adequate quality control in LTCs. The increased recognition
of the risk of scabies in LTCHs, particularly among patients and medical staff, has contributed to the decreased incidence of scabies. The Korean government has made concerted efforts to control scabies in LTCHs, including the publication of manuals for the prevention and management of scabies by the Korean Center for Disease Control and the adoption of a reporting system for scabies. Since 2018, hospitals with more than 150 beds are required by law to have infection control rooms with specialized personnel. LTCHs provide regular education about scabies to medical staff, patients, and workers involved in patient care. In 2023, the Korean Dermatologic Association launched the Scabies Control Program to promote awareness about scabies in the general population, screen for and control scabies in LTCHs, and establish practical guidelines for the diagnosis and management of scabies \(^{1,13}\).

A subgroup analysis disaggregated by sex showed the predominance of female patients with scabies. The longer average life span, greater sensitivity to itching or skin rashes, and hospital-seeking behavior of females might have contributed to this result. In a subgroup analysis disaggregated by region, the highest number of scabies cases was in Seoul and Gyeonggi which have several LTCHs. However, given that these regions have a greater population than other regions, we calculated the regional incidence rates by dividing the number of incident cases by the number of registered residents. A consistently high regional incidence was noted in several provinces during the last 12 years, particularly in Gwangju, Jeonnam, Jeonbuk, Daejeon, and Jeju. Whether scabies is endemic to these regions remains inconclusive, and a detailed study of regional differences in the incidence of scabies is required to validate our results.

Some limitations of our study should be acknowledged. First, the diagnosis of scabies was not universally validated by microscopic investigations or dermoscopy. Both suspected cases of scabies and cases of confirmed or clinically diagnosed scabies were included. Second, prophylactic treatment with gamma-linoleic acid is often provided to all patients in LTCHs once a patient is diagnosed with scabies; this may have led to an underestimation of the number of patients. Third, considering that the registered population number was used as the denominator to calculate regional incidence rates, patients with scabies who visited hospitals outside their registered region of residence could not be counted properly.

CONCLUSION

This updated report on the nationwide incidence of scabies in Korea revealed a decreasing incidence in all age groups and the aging of affected patients over the last 12 years. Strategies that target elderly patients are required for the effective control of scabies, particularly interventions for controlling outbreaks in LTCHs. Outbreaks of respiratory infectious diseases affect the incidence of scabies, thus indicating that general hygiene and isolation are important for scabies control.
