Chromoblastomycosis is a chronic granulomatous or verrucous skin condition that is mainly caused by *Fonsecaea pedrosoi*, *Phialophora verrucosa*, and *Cladophialophora carrionii*1. The recent taxonomic revision of the genus *Fonsecaea* has recognized four species: *F. pedrosoi*, *F. monophora*, *F. nubica*, and *F. pugnacius*2. In this case report, we introduce the first case of *F. nubica* skin infection in Korea.

An 84-year-old female visited our clinic with a soft, micaceous, scaly plaque surrounded by an erythematous scarring on the left inner wrist and dorsal hand area. The patient could not recall its onset or any history of trauma, but she reported its chronic progression over several years, which was accompanied by a painful or burning sensation. The patient had no significant past history of illnesses. The KOH examination of the wrist lesion showed sclerotic cells. The fungal culture showed a black-gray velvety colony (Fig. 1A) with *Cladosporium*-type conidia (Fig. 1B). The skin biopsy obtained from the granulation tissue showed aggregated neutrophil infiltration and lymphohistiocytes on the peri-vascular area of the dermis. Sclerotic cells were identified in this area (Fig. 1C). The evaluation of homology was done using the Basic Local Alignment Search Tool on the GenBank database. The internal transcribed spacer (ITS) region of ribosomal DNA was identified as *F. nubica* (used primers were ITS1 and ITS4). Gene sequencing revealed 100% homology with strain CBS 121720 and CGMHD 0745. Identity with other *Fonsecaea* species were 97.55% with *F. pedrosoi* type strain CBS 271.37 and 96.30% with *F. monophora* type strain CBS 269.37 (Fig. 2). The patient was treated with 100 mg itraconazole taken orally twice a day. After nine months, three coin-sized, wart-like, granulomatous plaque lesions remained (Fig. 1D), and local cryotherapy was also applied. Two months after the combination treatment, the patient demonstrated a good clinical improvement.

Although the four *Fonsecaea* species have similar morphologies, they have different pathogenicity. *F. pedrosoi* and *F. nubica* appear to be exclusively associated with chromoblastomycosis, whereas *F. monophora* was found to cause chromoblastomycosis and infections in other organs, including the brain, gallbladder, and lymph nodes2. The presence of muriform cells (Medlar bodies or sclerotic cells) and the identification of an etiological agent in a microbiological culture are necessary to confirm the diagnosis of chromoblastomycosis3. *Fonsecaea* species are often misidentified due to their indistinct morphological features. Moreover, the re-classification of the genus *Fonsecaea* is being made by molecular genetics. For strain DUMC 0401, it was reported as *F. pedrosoi* in 2010 by Lim SW et al.4; its ITS sequence was 99.47% identical with that of the present case. Based on the results of the phylogenetic analysis, this strain should be
Fig. 1. (A) Dark black, velvety colony on fungal culture (B) *Cladosporium*-type conidia are observed on the slide culture. (C) Mixed inflammatory infiltrate with dark-brown sclerotic cells in the dermis (H&E, ×400) (D) Clinical picture of the patient’s wrist

Fig. 2. Phylogenetic tree of *Fonsecaea nubica* using the Neighbor-Joining method with ribosomal RNA gene ITS sequence. The optimal tree is shown with the sum of the branch length = 0.21440491. The percentage of replicate trees in which the associated taxa were clustered together in the bootstrap test (500 replicates) is shown next to the branches. The evolutionary distances were computed using the Maximum Composite Likelihood method. The evolutionary analyses were conducted in MEGA7.
reclassified as *F. nubica* (Fig. 2). It is possible that there had been previous unreported cases of chromoblastomycosis caused by *F. nubica* in Korea. The treatment of chromoblastomycosis is challenging as there is currently no treatment of choice. Many modalities, including systemic antifungal agents, immunomodulatory therapy, physical methods, photodynamic therapy, and surgical excision, have been used in previous reports. Itraconazole is the most commonly used first-line agent. A successful treatment with voriconazole or posaconazole has also been described. In this case, we were able to get good results using oral itraconazole, followed by a combination therapy with cryotherapy.

Keywords: *Fonsecaea nubica*
